TROPHIC STATUS AND ECOLOGICAL EVALUATION OF CHLOROPHYCEAE

N. SWARNALATHA* AND A. NARSING RAO

Phycology and River Ecology lab., Osmania University, Hyderabad, India. *Department of Medicine, Division of Preventive Medicine & Nutrition, College of Physicians & Surgeons of Columbia University, New York, N.Y. 10032.

Nutrient status and ecological studies of Chlorophyceae in two lentic water bodies has been studied for a period of two years. As compared with Volvocales and Zygnematales (desmids), Chlorococcalian flora of water bodies has shown a better representation with greater bulk among the Chlorophyceae. The greatest diversity could be seen in Banjara lake followed by O.U. semipermanent pond in which the water got dried up during summer. The presence of certain Chlorococcalian genera are also considered as the indices of eutrophication of water bodies. Desmids are better represented in O.U. pond when compared to Banjara lake indicating fresh water nature of water body.

Keywords: Ecology; Eutrophication; Indice.

Introduction

Pearsall¹ concludes that the waters harbouring green algea are different in chemical composition than those favouring diatoms and blue-green algae in large lakes. Munawar², holds the view that this is also true with respect to smaller bodies of water. According to Round³, the presence of chlorophyceae in eutrophic waters is due to their higher nutrient contents. The present work is aimed at to find out the ecological factors which govern the distribution and periodicity of various groups of green algae in the water bodies under present investigation.

Materials and Methods

Banjara lake is situated in Banjara Hills of Hyderabad city and O.U. pond is situated in Osmania University campus of Hyderabad. The water samples were collected and the sampling was done at monthly intervals for a period of two years. The water samples were analysed for the various physico-chemical factors by following standard methods^{4.5}. 100 ml of surface water samples were also collected for the qualitative and quantitative estimation of algae by following the drop method of Pearsall *et al.*⁶ and as described by Venkateswarlu⁷.

Multiple Regression Analysis (MRA) - A statistical approach which was introduced by Nageswar Rao⁸, has been employed in order to evaluate the relative importance of various physico-chemical factors on the growth and development of chlorococcalian genera.

Results and Discussion

The results of various physico-chemical factors are given in Table 1 & 2. The two lakes are alkaline in nature with pH ranges from 7.8 to 9.8. Temperature fluctuated between 21 to 33 degrees centigrade. All the physico-chemical factors are in somewhat higher concentration when compared to O.U pond.

Volvocales are represented by Phacotus lenticularis in both water bodies. Pandorina, Gloeocystis and Sphaerocystis species are observed in O.U pond. Chlorococcales are represented by the species of Scenedesmus, Tetraedron in both lake and pond. Apart from these, Banjara lake is also represented by species of Dictyosphaerium. Ankistrodesmus, Kirchneriella, Coelastrum. Pediastrum, Micractinium etc. Desmids are represented by three genera, Closterium, Cosmarium and Pleurotaenium.

In Banjara lake, simple correlation analysis (SCA) reveals that except bicarbonates, chlorides, silicates total and dissolved solids, all are significant individually at both 5% and 1% level. MRA reveals that D.O, organic matter and dissolved solids together account for 25% variation in chlorococcales (Table-3, Fig-1). Griffiths⁹ holds the view that higher concentrations of D.O in water are favourable for the development of chlorococcales. Chlorococcales have attained their maximum peaks during summer when the temperatures were high with moderately high total solids in Banjara lake whereas the data was not observed in O.U. pond as the pond got dried up during summer. It is indicating that growth of chlorococcales is more or less connected to water temperature. This is in accordance with the observations of Rao^{10} and $Singh^{11}$. According to Round¹², eutrophic lakes also often have large summer growths of chlorococcales eg. Pediastrum, Scenedesmus, Dictyosphaerium, Crucigenia, Tetraedronetc which are all observed in Banjara lake. These are considered as the indices of degree of eutrophication of water body. Eutrophic waters are characterised by the species of Microcystis, Oscillatoria etc which are also observed in Banjara lake. This is in concurrence with the observations of Patrick¹³ and Welch¹⁴. Biological estimations of degree of eutrophication is more informative than chemical determinations³, whereas the other pond which is free from Microcystis bloom. summer growths of chlorococcales and better representation of desmids indicates oligotrophic nature of water body. This is also in conformity with the observations of Brook¹⁵.

The reason for the meagre representation of volvocales in Banjara lake

could have been due to the continuous blooms of *Microcystis*, which was antagonistic to volvocales in Banjara lake. Similar trend was experienced by Seenayya¹⁶. This is also supported by Philipose¹⁷, who reported the presence of large number of volvocales in the fish ponds of Bengal when they are only free from *Microcystis*. In the present investigation, O.U. pond which is free from *Microcystis* bloom supported somewhat better representation of volvocales which extends support to the above workers.

The poor representation of desmids could be due to eutrophic nature of water body in Banjara lake. Vanoye¹⁸ attributed paucity of desmids in Belgium waters to their eutrophic nature which is a complicated expression in terms of organic matter, oxygen, nutritional levels etc. Round¹² also points out that desmids are generally believed to favour oligotrophic waters. This is supported by the better distribution of desmids in O.U pond.

The total solids with their lowest concentration supported higher percentage of desmids and lower number of chlorococcales in O.U. pond whereas Banjara lake with moderately high total solids has supported lower number of desmids and higher number of chlorococcales. Gonzalves and Joshi¹⁹ observed a similar phenomenon during their investigation.

O.U. pond supported somewhat more number of desmids which were low in phosphates and nitrates concentration and somewhat higher concentration of phosphate in Banjara lake has coincided with the lower population of desmids. This is in concurrence with the observations of Pearsall²⁰, who while working in certain English lakes, has concluded that desmids occur in waters which are low in nitrates and phosphates concentrations.

The pH of water seems to be another factor influencing the growth of desmid populations. Strom²¹, Froehne²² are of the

Banjara Lake Multiple regression analysis of physico-chemical factors onChlorophyceae.

143

Swarnalatha & Rao

opinion that acidic waters support rich desmid flora. The pH was always less in O.U pond when compared to Banjara lake which is highly alkaline. According to Brook²³, the greatest species diversity of desmids has been described for waters of low alkalinity. This conforms the present data of low pH and better desmids in O.U pond whereas high pH and poor representation of desmids in Banjara lake.

All the physico-chemical variables together account for 98% of variation in chlorococcalian flora in O.U pond. Though the density of this algal flora is less, it has shown higher percentage because of less number of observations and more number of variables in O.U pond. MRA revealed that bicarbonates, total hardness, magnesium and silicates could contribute 59% variation in O.U. pond (Table-4, Fig-2).

To sum up the distribution of chlorococcales, it can be said that they are mainly influenced by temperature and total solid content of water. The large summer growths of chlorococcales and paucity of desmids in Banjara lake indicate eutrophic nature of water body. In O.U. pond better representation of desmids and which is free from algal blooms indicate oligotrophy. From the foregoing account, it is clear that both water bodies differed in the concentration of various physico-chemical factors which probably account for the variation in the species composition and density of flora because the physico-chemical factors are more intimately connected with algal flora, especially in lentic environments.
